

* Pauli gates.

$ZX = iY$, X, Y, Z are pairwise 'anti-commute'.

e.g. $XY = -YX$.

* Pauli group: $G(n)$. is a set of n -qubit unitaries that are generated from $\{I, X, Y, Z\}$ by tensor product and composition.

e.g. $G(1) = \{\pm I, \pm iI, \pm X, \pm iX, \pm Z, \pm iZ, \pm iY, \pm Y\}$. ($|G(1)| = 4^{n+1}$)

$$G(2) = \{ a P_1 \otimes P_2 \mid a \in \{\pm 1, \pm i\}, P_1, P_2 \in G(1) \}$$

side note: G is a group if G is a set that is equipped with $e \in G$, $*$: $G \times G \rightarrow G$.

$$\text{inv}: G \rightarrow G \quad \text{s.t.}$$

$$e * g = g, \forall g \in G$$

$$\text{inv}(g) * g = g * \text{inv}(g) = e, \forall g \in G,$$

$$(g_1 * g_2) * g_3 = g_1 * (g_2 * g_3).$$

We write $S \trianglelefteq G$ if S is a subgroup of G .

* Stabilizer states and stabilizers.

Let $S \triangleleft \mathcal{A}(n)$, the stabilizer states of S , denoted by V_S , is the set

$$V_S = \left\{ \phi \mid \phi \in \mathbb{C}^{2^n} \forall P \in S, P(\phi) = \phi \right\}$$

↑ complex vector space of dim 2^n .

Thm: V_S is a vector space.

e.g. if $a, b \in V_S$, $a + b \in V_S$. $(P(a+b) = P(a) + P(b) = a + b)$

$\forall c \in \mathbb{C}, a \in V_S, ca \in V_S$. etc. $(P(ca) = cP(a) = ca)$

S is call "stabilizer" of V_S .

* Example: $\mathbb{D} S = \{ \underline{I}, \underline{ZZI}, \underline{IZZ}, \underline{ZIZ} \}$
 $= \langle \underline{ZZI}, \underline{IZZ} \rangle$

We write \underline{ZZI} for $Z \otimes Z \otimes I$.

$$V_{\underline{ZZI}} = \langle |000\rangle, |001\rangle, |110\rangle, |111\rangle \rangle$$

↑ vector space 'spanned' by ...

$$V_{\underline{IZZ}} = \langle |000\rangle, |011\rangle, |100\rangle, |111\rangle \rangle$$

So $V_S = V_{\underline{ZZI}} \cap V_{\underline{IZZ}} = \langle |000\rangle, |111\rangle \rangle$

$$\textcircled{2} S = \langle XX, ZZ \rangle$$

$$V_{XX} = \langle |+\rangle, |-\rangle \rangle$$

$$V_{ZZ} = \langle |00\rangle, |11\rangle \rangle$$

$$V_S = V_{XX} \cap V_{ZZ} = \left\langle \frac{|00\rangle + |11\rangle}{\sqrt{2}} \right\rangle = \frac{|++\rangle + |--\rangle}{\sqrt{2}}$$

* we write

$$S = \langle P_1, \dots, P_L \rangle$$

to mean S is generated from $P_1, \dots, P_L \in Q(n)$
and P_i, P_j are independent.

We assume P_i, P_j commutes

and $P_i \neq -I \forall i$.

Thm: Let $S = \langle P_1, \dots, P_L \rangle$ satisfying
the assumption. Then we have.

$$\dim(V_S) = 2^{n-l}$$

* Modeling Clifford Computation, rather than working with state explicitly, we work with the stabilizer instead.

so $\langle Z \rangle$ instead of $|0\rangle$

$\langle ZI, IZ \rangle$ instead of $|00\rangle$

$\{H, S, CNOT\}$

then: Applying a Clifford gate on to a state can be described as 'group action', i.e. conjugation.

e.g. $\langle Z \rangle \xrightarrow{H} \langle HZH \rangle = \langle X \rangle$

$\left. \begin{array}{l} \text{Stabilizes} \\ \{ \end{array} \right\}$
 $\left. \begin{array}{l} \text{Stabilizes} \\ \{ \end{array} \right\}$

$|0\rangle \xrightarrow{H} |1\rangle$

e.g. $\langle ZI, IZ \rangle \xrightarrow{H \otimes I} \langle XI, IZ \rangle$

$\left. \begin{array}{l} \{ \\ \{ \end{array} \right\}$
 $\left. \begin{array}{l} \{ \\ \{ \end{array} \right\}$

$|00\rangle \xrightarrow{H \otimes I} |1\rangle|0\rangle$

This is because $\forall g \in S, \phi \in V_S,$

$$(U|\phi\rangle) = U g |\phi\rangle = \underline{U g U^\dagger} (U|\phi\rangle)$$

So if g stabilizes $|\phi\rangle,$

$U g U^\dagger$ stabilizes $U|\phi\rangle.$

* Side note. This is an example of a group G 'acting' on a set X .

$$e \cdot x = x$$

$$g_1 \cdot (g_2 \cdot x) = (g_1 * g_2) \cdot x$$

~~So~~ So for $g \in S,$

$$U \cdot g = U g U^\dagger.$$

* Since $g \in G(n),$ it would be nice if $U g U^\dagger \in G(n).$ Unfortunately, this is not true in general. Only the so-called "Clifford gates" have this property.

* Some useful identities.

$$\begin{array}{l}
 H \cdot X = Z \\
 H \cdot Z = X
 \end{array}
 \left(
 \begin{array}{l}
 S \cdot X = Y \\
 S \cdot Z = Z \\
 (S \cdot X = SXst)
 \end{array}
 \right)$$

$$CX \cdot (X \otimes I) = X \otimes X$$

$$CX \cdot (I \otimes X) = I \otimes X$$

$$CX \cdot (Z \otimes I) = Z \otimes I$$

$$CX \cdot (I \otimes Z) = Z \otimes Z$$

Thm: Let $C = \langle H, S, CX \rangle$.

$\forall D \in C, P \in GL(n)$, we have $D \cdot P \in GL(n)$

Thm: More surprisingly, for any group K ,

if $\forall D \in K, P \in GL(n), D \cdot P \in GL(n)$,

then $K = \langle H, S, CX \rangle$.

* Measurements.

Projective measurement.

Let M be hermitian.

$$\text{If } M = \sum_i m_i P_i$$

$$P_i P_j = 0 \text{ if } i \neq j.$$

where $M(P_i(\phi)) = m_i P_i(\phi)$

(m is an eigenvalue of M)

then

"measure ϕ in M -basis," means

applying one of the P_i to ϕ .

the probability of getting the result

m_i is $p(m_i) = \langle \phi | P_i | \phi \rangle$.

The average value of the measurement is:

$$E(M) = \sum_i p(m_i) \cdot m_i$$

$$= \sum_i \langle \phi | P_i | \phi \rangle \cdot m_i$$

$$= \langle \phi | \sum_i m_i P_i | \phi \rangle$$

$$= \langle \phi | M | \phi \rangle.$$

* So when people say "measure of $g \in \mathcal{A}$ " they mean g is hermitian and they do projective measurement of g .

* Fun fact.

① if $g \in U(n)$ is a product of Paulis without -1 or $\pm i$. then

g has only 2 eigenvalues, they are ± 1 .

$$\text{and } g = \left(\frac{I+g}{2} \right) - \left(\frac{I-g}{2} \right)$$

$$g \left(\frac{I+g}{2} |\psi\rangle \right) = \frac{I+g}{2} |\psi\rangle$$

$$g \left(\frac{I-g}{2} |\psi\rangle \right) = - \frac{I-g}{2} |\psi\rangle$$

Note that

$$\left(\frac{I+g}{2} \right) \cdot \left(\frac{I-g}{2} \right) = \frac{I-g+g-g \cdot g}{4} = \frac{I-g+g-I}{4} = 0.$$

so $\frac{I+g}{2}$ and $\frac{I-g}{2}$ are orthogonal.

* If the stabilizer S of $|\psi\rangle$'s
 $\langle g_1, \dots, g_n \rangle$, and g is hermitian,
 then measure on g basis.
 will result in the following two cases.

① Suppose g commute with g_1, \dots, g_n .

In this case either g or $-g \in S$.

because $\forall |\psi\rangle \in V_S = \langle |\psi\rangle \rangle$

$$g_i(g|\psi\rangle) = (g_i g)|\psi\rangle = (g g_i)|\psi\rangle$$

$$= g(g_i|\psi\rangle) = g|\psi\rangle \quad \forall g_i$$

$$\text{So } g|\psi\rangle \in V_S$$

$$\Rightarrow g|\psi\rangle = a|\psi\rangle \quad a \in \mathbb{C}$$

$$|\psi\rangle = g g|\psi\rangle = g(a|\psi\rangle) = a g|\psi\rangle = a^2 |\psi\rangle$$

$$\Rightarrow a^2 = 1 \quad \Rightarrow a = \pm 1$$

So either g or $-g \in S$.

If $g \in S$, i.e. $g|\varphi\rangle = |\varphi\rangle$.

$$\text{then } \frac{I+g}{2} |\varphi\rangle = |\varphi\rangle.$$

$$\frac{I-g}{2} |\varphi\rangle = 0.$$

So g -measurement always return +1 result and the state $|\varphi\rangle$ is unchanged after the measurement!

If $-g \in S$, i.e. $g|\varphi\rangle = -|\varphi\rangle$.

$$\text{then } \frac{I+g}{2} |\varphi\rangle = 0$$

$$\frac{I-g}{2} |\varphi\rangle = |\varphi\rangle.$$

So g -measurement always return -1 and $|\varphi\rangle$ is unchanged.

② if g anti-commutes with g_1 . Note that if g also anti-commutes with g_2 , we can set

$$S = \langle g_1, g_1 g_2, g_3, \dots, g_n \rangle = \langle g_1, g_2, \dots, g_n \rangle$$

and $g_1 g_2$ commutes with g

So Without loss of generality, we can assume g only anti-commutes with g_1 .

$$P(+1) = \langle \psi | \frac{I+g}{2} | \psi \rangle$$

$$= \frac{1 + \langle \psi | g | \psi \rangle}{2}$$

$$P(-1) = \langle \psi | \frac{I-g}{2} | \psi \rangle = \frac{1 - \langle \psi | g | \psi \rangle}{2}$$

$$\langle \psi | g | \psi \rangle = \langle \psi | g g_1 | \psi \rangle$$

$$= -\langle \psi | g | \psi \rangle$$

$$(g_1 = g_1^\dagger)$$

$$= -\langle \psi | g | \psi \rangle$$

$$\Rightarrow \langle \psi | g | \psi \rangle = 0.$$

So with $\frac{1}{2}$, we get +1

and the resulting

$$\text{state } \frac{I+g}{2} |\psi\rangle$$

$$\forall i \neq 1 \quad g_i \left(\frac{I+g}{2} \right) |\psi\rangle = \frac{g_i + g_i g}{2} |\psi\rangle$$

$$= \frac{g_i + g_i g_i}{2} |\psi\rangle$$

$$= \frac{I+g}{2} g_i |\psi\rangle$$

$$= \frac{I+g}{2} |\psi\rangle$$

$$\text{and } g \left(\frac{I+g}{2} |\psi\rangle \right) = \frac{I+g}{2} |\psi\rangle.$$

So $\frac{I+g}{2} |\psi\rangle$ is stabilised by

$$\langle g_1, g_2, \dots, g_k \rangle.$$

Similarly, with $\frac{1}{2}$, the resulting state

is stabilised by $\langle -g_1, g_2, \dots, g_k \rangle$.
